Abstract
A new method for color image segmentation using fuzzy logic is proposed in this paper, to automatically produce a fuzzy system for color classification and image segmentation with least number of rules and minimum error rate. We use particle swarm optimization (PSO) technique to find optimal fuzzy rules and membership functions. PSO is a sub class of evolutionary algorithms that has been inspired from social behavior of fishes, bees, birds, etc. that live together in colonies. Here each particle of the swarm codes a set of fuzzy rules. Finally, particle with the highest fitness value is selected as the best set of fuzzy rules for image segmentation. Our results, using this method for soccer field image segmentation in Robocup contests shows 89% performance. Less computational load is needed when using this method compared with other methods like ANFIS. Large train dataset and its variety, makes the proposed method invariant to illumination noise.

Keywords: fuzzy colour classification, particle swarm optimization

1 Introduction

The process of partitioning a digital image into multiple regions (sets of pixels) is called image segmentation. Actually, partitions are different objects in image which have the same texture or color. The result of image segmentation is a set of regions that collectively cover the entire image, or a set of contours extracted from the image. All of the pixels in a region are similar with respect to some characteristic or computed property, such as color, intensity, or texture. Adjacent regions are significantly different with respect to the same characteristics. Some of practical applications of image segmentation are: image processing, computer vision, face recognition, medical imaging, digital libraries, image and video retrieval, etc [1].

Image segmentation methods fall into five categories: Pixel based segmentation [2], Region based segmentation [3], Edge based segmentation [4], [5], Edge and region Hybrid segmentation [6] and Clustering based segmentation [7], [8], [9], [10], [11]. Color image segmentation using fuzzy classification is a pixel based segmentation method. A pixel is assigned a specific color by the fuzzy system. One approach in designing such a fuzzy system is an expert to look at training data and try to manually develop a set of fuzzy rules. Two drawbacks with such method are that first it is very cumbersome and time consuming and second there is no guarantee that the produced fuzzy rules are the best possible ones. So, there is need for a method which could produce fuzzy rules and membership functions automatically.

Several methods have been proposed in literature for automatic production of fuzzy rules like genetic algorithms and ANFIS [12], [13], [14], [15]. One problem with these methods is that they generate a large number of fuzzy rules which causes slow classification and processing speed [8]. In this paper, we propose a method which produces a smaller number of rules while preserving low error rate. To that aim we use PSO to search for a set of such fuzzy rules.

The rest of this paper is organized as follows: in section two, fuzzy colour classification is explained. An introduction to comprehensive learning particle swarm optimization is illustrated in section three. In section four we give the details of our proposed method for fuzzy color image segmentation using PSO. Our experimental setup and results are shown in section five. Finally, conclusions and discussions come in section six.

2 Fuzzy Colour Classification

Fuzzy color classification is a supervised learning method for segmentation of color images. This method assigns a color class to each pixel of an input image by applying a set of fuzzy rules on it. A set of training image pixels, for which the colors are known are used to train the fuzzy system. The trained fuzzy system will be later evaluated on test images.

Different color spaces like HSL, RGB, YIQ, etc. have been suggested in image processing, each suitable for different domains [1]. In this study, we chose HSL color space because a color in this space is represented in three dimensions: one which codes the
color itself (H) and another two which explain details of the color, saturation (S) and lightness (L). Because of this segregation of color components, this color space is most suitable for our purpose [1].

As it can be seen in Fig. 1, H dimension is shown in a circle with colors occupying a range of degrees around it. Instead of assigning a specific hue value to each color around this circle, a fuzzy membership function can code for a color by giving it a range of hues each with different membership value. As an example, H dimension in Fig. 2 is partitioned into ten trapezoidal membership functions each one coding a different color.

![Fig. 1 HSL color space.](image)

![Fig. 2 Partitioning H dimension with trapezoidal fuzzy membership functions](image)

Trapezoidal membership function showed in Fig. 3 needs four parameters to be specified [1].

![Fig. 3 trapezoidal fuzzy subset](image)

To represent two remaining dimensions of a color, because of their less importance for determining a color compared with Hue dimension, we divide each dimension to three parts: weak, medium and strong. Combining these two dimensions we come to nine regions for representing a color shown in Fig. 4.

![Fig. 4 Color representation on S and L dimensions](image)

A two dimensional membership function is then placed on each region. In order to generate two dimensional membership functions, three 1D trapezoidal membership functions is placed over each dimension and then by multiplying these functions a set of nine 2D membership functions is generated. Following figure illustrates above concept.

![Fig. 5 Fuzzy memberships on S and L](image)

Each fuzzy rule is represented as follows:

\[ \text{j-th rule:} \]
\[ \text{if } x_i \text{ is } A_{i_1} \text{ and } x_j \text{ is } A_{j_1} \text{ and ... and } x_k \text{ is } A_{k_1} \text{ then } \mathbf{z} = (x_1, x_2, ..., x_m) \text{ belongs to class } H_j \]
\[ \text{with } CF_j = CF_j \quad j = 1, 2, ..., R \]

(1)

in which R is the number of fuzzy rules, m is the dimensionality of input vector, \( H_j \in \{1, 2, ..., M\} \) is output of the jth rule, M is the number of color classes, \( CF_j \in [0, 1] \) is the certainty factor of jth rule.

We tried three types of membership functions in our experiments. Equation (2), gives an example of how we code membership functions on a Gaussian membership function.

\[ \mu_{A_j}(m_{i,j,1}, m_{i,j,2}, m_{i,j,3}, x_i) = \]
\[ \begin{cases} 
\exp \left( -\frac{x_i - m_{i,j,1}}{m_{i,j,2}} \right) & \text{if } x_i \leq m_{i,j,2} \\
\exp \left( -\frac{x_i - m_{i,j,3}}{m_{i,j,2}} \right) & \text{if } x_i > m_{i,j,3} 
\end{cases} \]

(2)
in above equation, \( m_{p,d} = [m_{p,d,1}, m_{p,d,2}, ..., m_{p,d,r}] \) are the parameters of the \( d \)th membership function of \( j \)th rule. \( P \) is the number of parameters.

\[ L_j = [L_{j,1}, L_{j,2}, ..., L_{j,r}] \]

is the \( j \)th rule and \( r = [L_{j,1}, L_{j,2}, ..., L_{j,r}] \) represents the whole fuzzy rule base. \( g[H_j, C_{j,1}, H_j, C_{j,2}, ..., H_j, C_{j,2}] \) is the input of the fuzzy rule base. When an input vector \( x = (x_1, x_2, ..., x_n) \) is presented to the system, output of the system is calculated as:

\[
q_j(x) = \prod_{i=1}^{n} \mu_{j,i}(x_i)
\]

\[
y = \arg\max_{j} q_j(x) * CF.
\]

Classification performance of a fuzzy system is very much dependent on its parameters. We are going to use a global search method (Comprehensive learning particle swarm optimization) to find a rule base with both minimum number of rules and minimum error rate.

3 Particle Swarm Optimization

Particle Swarm Optimization (PSO) is a recently proposed algorithm by James Kennedy and R. C. Eberhart in 1995, motivated by social behavior of organisms such as bird flocking and fish schooling [17, 18]. PSO as an optimization tool provides a population-based search procedure in which individuals called particles change their position (state) with time [19]. In PSO, individuals represent points in the \( n \)-dimensional search space [20]. A particle represents a potential solution. The velocity \( V_i^d \) and \( X_i^d \) position of the \( d \)th dimension of the \( i \)th particle are updated as follows:

\[
V_i^d \leftarrow V_i^d + c_1 * rand1^d * (pbest^d - X_i^d) + c_2 * rand2^d * (gbest - X_i^d)
\]

\[ X_i^d \leftarrow X_i^d + V_i^d \]  

Where \( X_i = (X_i^1, X_i^2, ..., X_i^n) \) is the position and \( V_i = (V_i^1, V_i^2, ..., V_i^n) \) is the velocity of particle \( i \) [21][22]. \( pbest = (pbest^1, pbest^2, ..., pbest^n) \) is the best position previously yielded the best fitness value for the \( i \)th particle and \( gbest = (gbest^1, gbest^2, ..., gbest^n) \) is the best position discovered by the whole population. \( c_1 \) and \( c_2 \) are the acceleration constants reflecting the weighting of stochastic acceleration terms that pull each particle toward \( pbest \) and \( gbest \) positions respectively[23]. \( rand1^d \) and \( rand2^d \) are two random numbers in the range \([0, 1]\). A particle’s velocity on each dimension is clamped to a maximum magnitude \( V_{max}\). If \( |V_i^d| \) exceeds a positive constant value \( V_{max}^d \) specified by the user, then the velocity of that dimension is assigned to \( sign(V_i^d) * V_{max}^d \).

When updating the velocity of a particle using (4), different \( rand1^d \) and \( rand2^d \) dimensions have different and. Some researchers use the following updating equation:

\[
V_i^d \leftarrow V_i^d + c_1 * rand1^d * (pbest^d - X_i^d) + c_2 * rand2^d * (gbest - X_i^d)
\]

Comparing the two variants in (4) and (6), the former can have a larger search space due to independent updating of each dimension, while the second is dimension-dependent and has a smaller search space due to the same random numbers being used for all dimensions.

4 PSO based fuzzy classification

Population \( P \) with \( L \) particles is represented as a vector:

\[
P = \begin{bmatrix}
L_1 & L_2 & L_3 \\
L_1 & L_2 & L_3 \\
L_1 & L_2 & L_3 \\
L_1 & L_2 & L_3
\end{bmatrix}
\]

\[ P = [L_1, L_2, ..., L_L] \]

Is a member of population, and exemplify a fuzzy rule base[2]. The parameter vector \( L_j = [L_{j,1}^1, L_{j,2}^1, L_{j,3}^1, ..., L_{j,r}^1] \) consists of the premise parameters of the candidate fuzzy rules, where \( B \) is a user-defined positive integer to decide the maximum number of fuzzy rules. \( L_j = [m_{j,1}^1, m_{j,2}^1, ..., m_{j,r}^1] \) is the membership functions of the \( j \)th rule in which \( M \) codes for the number of inputs of the system. \( m_{j,p,d} = [m_{j,p,d,1}, m_{j,p,d,2}, ..., m_{j,p,d,r}] \) is the \( d \)th membership function of the \( j \)th rule in which \( p \) is the number of parameters of each membership function.

In order to be able to reduce the number of rules we used vector \( g_{s} = [g_{s,1}, g_{s,2}, ..., g_{s,L}] \). In fact for each rule \( L_j \) there exists an element \( g_{s,j}^* \). If \( g_{s,j}^* \geq 0.5 \) then the corresponding rule is considered eligible for adding to the rule base. Let \( r_n \) be the number of acceptable rules, then index of these rules and their representation are: \( L_{j,1}, L_{j,2}, ..., B \), \( r = 1, 2, ..., r_n \).

\( [L_{j,1}^1, L_{j,2}^1, L_{j,3}^1, ..., L_{j,r}^1] \) respectively. Consequently, the rule base of the generated fuzzy classification system is described as follows:
\( r \)-th rule:
\[
\begin{align*}
&\text{if } \text{x is } A_i^b, \quad \text{and x is } A_j^b, \text{and... and x is } A_m^b, \quad \text{then } y = (x, x_1, ..., x_n) \text{ belongs to class } H_r, \\
&\text{with } CF = CF_r, \quad r = 1, 2, ..., r,
\end{align*}
\]
where \( A_i^b, i = 1, 2, ..., m \) are the fuzzy sets of the \( r \)-th generated fuzzy rule.

To completely define each rule, certainty factor \( CF \) and output \( H \) must be determined [2]. To that purpose, we use a set of training data. There are \( N \) training data patterns, each belonging to one of \( M \) colors. Each training pattern is represented by a vector \((x_m, y_m), n = 1, 2, ..., N \) in which
\[
\hat{x}_m = (x_{m1}, x_{m2}, ..., x_{mn}) \quad \text{and} \quad y_m \in \{1, 2, ..., M\}
\]
are input and output of \( r \)-th sample respectively.

For the \( r \)-th rule, \( CF \) and \( H \) are determined as follows:

\[
\begin{align*}
1) & \quad \theta_r = \sum_{i \in \text{class}} q_r(x_i), t = 1, 2, ..., M \\
2) & \quad H_r = \arg \max_{r} \theta_r \\
3) & \quad \text{Determine the grade of certainty } CF_r \text{ of the } \text{r-th fuzzy rule by:}
\end{align*}
\]
\[
\begin{align*}
CF_r = & \frac{\theta_r}{\sum_{i \in \text{class}} \theta_i}, \quad \theta = \sum_{i \in \text{class}} \theta_i \\
\end{align*}
\]
where, \( \theta = \sum_{i \in \text{class}} \theta_i / M - 1 \)

Fitness of each particle should satisfy two criteria when selecting rule bases. A rule base is better if it has less number of rules and minimum error rate. An example of such a fitness function is:
\[
f_p = \text{fit}(p_k) = g_1(p_k) + g_2(p_k)
\]
in above equation, functions \( g_1 \) and \( g_2 \) serve for the first and second criteria correspondingly.
\[
\begin{align*}
&g_1(p_k) = \exp (-\frac{\text{NICP}(p_k)}{\alpha}) \\
&g_2(p_k) = \exp (-\frac{\beta}{\alpha})
\end{align*}
\]
\( \text{NICP}(p_k) \) is the number of false classified patterns. Gradually, in the course of running algorithm, particles try to find rule bases which maximize the fitness function. To put all things together, we describe the method in an algorithmic step-wise manner as follows:

**Step 1)** Initialize the PSO-based method.

General parameters of the algorithm are listed in Table 1.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Symbol</th>
<th>Initialization value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Population size</td>
<td>( L )</td>
<td>Variable</td>

<td>5,10</td>
</tr>
<tr>
<td>Constants of PSO</td>
<td>((b, d_1, d_2, \epsilon))</td>
<td>((1,1,0.7))</td>
</tr>
</tbody>
</table>

Each member of the population \( p_k = [p_{1k}, g_{1k}] \) is randomly initialized as follows:
\[
p_{1k} = [m_{1k}^0, m_{12}^0, ..., m_{1k}^0, m_{12}^0, ..., m_{1k}^0, m_{1m}^0, m_{21}^0, ..., m_{2k}^0, ..., m_{2m}^0, m_{m1}^0, ..., m_{mk}^0, ..., m_{mm}^0]
\]
\[
g_{1k} = [g_{1k}^0, g_{2k}^0, ..., g_{k}^0]
\]
\[
\begin{align*}
&\text{and } g_{1k} = [g_{1k}^0, g_{2k}^0, ..., g_{k}^0], m_{j,k} = [m_{j1,k}, m_{j2,k}, ..., m_{j,k}], \\
&j = (1,2,...,B), \quad i = (1,2,...,M), \quad k = (1,2,3)
\end{align*}
\]
is randomly generated as follows:
\[
m_{j,k} = m_{j,k}^{\text{min}} + (m_{j,k}^{\text{max}} - m_{j,k}^{\text{min}}) \cdot \text{rand}() (16)
\]
where the range of the parameter \( m_{j,k}^{\text{min}}, m_{j,k}^{\text{max}} \) is determined as \( [m_{j,k}^{\text{min}}, m_{j,k}^{\text{max}}] \).

Velocity vector \( v_{1k} = (v_{11k}, ..., v_{1Lk}) \) of a particle is initialized randomly as:
\[
\begin{align*}
&v_{1k} = [\alpha_{1k}, \beta_{1k}] \\
&\alpha_{1k} = [\alpha_{11k}, \alpha_{12k}, ..., \alpha_{11k}, \alpha_{12k}, ..., \alpha_{11k}, \alpha_{12k}, ..., \alpha_{11k}, \alpha_{12k}, ..., \alpha_{11k}] \\
&\beta_{1k} = [\beta_{11k}, \beta_{12k}, ..., \beta_{11k}, \beta_{12k}, ..., \beta_{11k}, \beta_{12k}, ..., \beta_{11k}, \beta_{12k}, ..., \beta_{11k}]
\end{align*}
\]
\( \alpha_{1k}, \beta_{1k} \) are calculated as follows:
\[
\begin{align*}
&\alpha_{1k} = \frac{m_{j,k}^{\text{max}} - m_{j,k}^{\text{min}}}{20} \cdot \text{rand}() \\
&\beta_{1k} = \frac{\text{rand}()}{20}
\end{align*}
\]

**Step 2)** calculate the fitness value of the individual and set initial \( f_{p_{1k}} \) for each individual an initial \( p_{1k}^{\text{best}}, f_{p_{1k}}^{\text{best}} \) for the initial population.
\[
f_{p_{1k}} = \text{fit}(p_{1k}), \quad h = 1, 2, ..., L
\]
\[
\begin{align*}
&f_{p_{1k}} = f_{p_{1k}}, p_{1k} = p_{1k}, \quad h = 1, 2, ..., L
\end{align*}
\]
Find the index $j$ of the individual with the best fitness

$$J = \arg\max f_j$$

$$f^{best} = f_j, p^{best} = p_j$$ (24)

gen = 1

Step 3) Update $g_p = [g^b_1, g^b_2 \ldots g^b_j \ldots g^b_{j^*}]$:

if $\psi \geq \text{rand}(0)$ then

$$g^b_j = 1 - g^b_j, f' = \text{rand}(B \text{ rand}(0) + 0.5)$$ (23)

Step 4) Update $P_p, s_p$ and $p^{best}, f^{best}$

Update $P_p, f_p$ in the following: Calculate $f_p = \text{fit}(p)$

if $f_p > f_j$, then $f_j = f_p, p_j = p_p, h = 1, 2, \ldots, L$

Update $P^{best}_p, f^{best}$ in the following:

if $f_j > f^{best}$, then $f^{best} = f_j, P^{best}_p = p_j, h = 1, 2, \ldots, L$

Step 5) Update velocity $v_p$ and position $p_p$ as follows:

$$v_p = v_p + c_1 \cdot \text{rand}(0.1) (P^{best}_j - P_p)$$ (24)

$$+ c_2 \cdot \text{rand}(0.1) (P_p - P_{p-1}), h = 1, 2, \ldots, L$$

Update the parameter vectors in the following:

$$P_p = v_p + P_p, h = 1, 2, \ldots, L$$ (25)

Step 6) Decay Velocities:

$$v_p = v_p \cdot d_1, d_1 \in [0, 1]$$ (26)

$$v_p = v_p \cdot d_2, d_2 \in [0, 1]$$

Step 7) Check Stopping Criteria:

gen = gen + 1 (27)

if gen $> K$ or the average velocity of particles surpasses a small threshold near zero then go to next step, else go to step 5.

Step 8) Stop: Report particle with the best fitness value as best rule base.

5 Experiments and results

In this section, details of our implementation and experimental results are presented. To evaluate the efficiency of this method we conducted experiments on segmentation of color images taken from a Robocup football field which is a benchmark problem in robotic contests.

5.1 Training Data

Color images taken from a small size Robocup soccer field are used as training data. Because we were to build a segmentation system invariant to illumination, we tried to choose images taken at different lightening situations. Each training point belongs to one of ten color classes (Red1, Orange, Yellow, Green, Cyan, Blue, Purple, Magenta, Pink, Red2). (Red1 and Red2 correspond to first and last membership function in Hue dimension). A total number of 9,000 training data and 3,000 test data were used. From 1,200 data points available for each class, 900 was used for training and remained 300 for testing.

5.2 Fuzzy system Structure

We used a Sugeno-type Fuzzy inference system with three inputs consisting dimensions of HSL color space. Ten membership functions for H dimension and three for each S and L dimensions was used. Ten constant membership functions were put on output variable. Three types of membership functions trapezoidal, Gaussian and Bell-shaped were investigated for the purpose of their comparison over this problem. Maximum and minimum of membership functions are determined according to [1]. Our results rank membership functions as Bell-shaped, Gaussian and trapezoidal respectively according to their performance.

5.3 Algorithm Parameters

We manually set values for parameters based on previous studies and problem characteristics. Those values are listed in Table 1.

5.4 Initial Population Generation

Proper initialization of particles plays an important role in algorithm efficiency. We compared two initialization methods, randomly generating rules and rule generation using neuro-fuzzy method. In order to generate fuzzy rules, we used ANFIS toolbox provided with MATLAB® programming environment.

<table>
<thead>
<tr>
<th>TABLE II</th>
<th>ANFIS PERFORMANCE</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trapezoidal membership function</td>
<td>Gaussian membership function</td>
</tr>
<tr>
<td>Number of rules</td>
<td>Accuracy</td>
</tr>
<tr>
<td>90</td>
<td>60%</td>
</tr>
</tbody>
</table>

<table>
<thead>

</tr>
<tr>
<td>rules</td>
<td>Accuracy</td>
</tr>
<tr>
<td>Random</td>
<td>40</td>
</tr>
<tr>
<td>ANFIS</td>
<td>47</td>
</tr>
</tbody>
</table>

As it is shown in Table III, a higher performance is achievable with ANFIS initialization compared with random method. The reason might be that we
constrain the maximum number of iterations which is needed for algorithm to be computationally tractable. The total number of rules generated with this method is about one third of the average number of rules generated with ANFIS.

An example of running our method to segment a soccer field image is shown in Fig. 6. Top row shows the performance of our method with ANFIS initialization and Bell-shaped membership functions. Bottom row illustrates the performance of ANFIS method. Images at the left are originals and those at the right are segmented ones.

Fig. 6 Segmented Image with PSO-based fuzzy method

6 Conclusions

A new method for segmentation of color images using a PSO-based fuzzy system was introduced in this paper. A particle of the swarm codes for a set of fuzzy rules. A fitness function rates for the Optimality of each particle. During iterations, particles try to maximize fitness function by cooperatively working on search space. This process is continued until either maximum number of iteration is met or average velocity approaches zero. Finally, the rule base represented by the best particle is used for the task of image segmentation. Because of smaller number of rules generated by this method, it shows higher computation speed. Using PSO for searching in the space of all possible solutions we achieved a better solution in terms of small size and high performance compared with ANFIS. Because we used a large training set including images taken at different illuminations, this method is robust to variations in illumination.

Paper Title: Soccer Field Image Colour Segmentation using PSO-based Fuzzy

On behalf of the organising committee of the 4th International Conference on Computational Intelligence Robotics and Autonomous Systems 2007 (CIRAS 2007), I am pleased to inform you that your above mentioned paper has been accepted for presentation at CIRAS, November 28-30, 2007 at Palmerston North, New Zealand. Please note that your submitted full paper requires some revision. Reviewer's reports are attached along with this email. Please submit your revised paper by 21st September 2007 addressing the questions/comments raised by the reviewers (if any). Your paper MUST conform to the formatting guidelines before it can be printed in the conference proceedings; please pay close attention to the formatting details. The formatting guidelines are provided.

Please send your camera ready paper in WORD (.doc) format as an email attachment to S.C.Mukhopadhyay@massey.ac.nz . The file name of your paper should be CIRAS2007074.doc

To ensure CIRAS maintains the highest possible standards, your full paper was peer reviewed by international experts before being accepted.

Unless one of the authors of an accepted paper registers for the conference, the paper will not be published in the proceedings. Please note that the deadline for author registration is September 28, 2007.

Presentation guideline is available on the CIRAS website at:
http://ciras.massey.ac.nz/presentation_guidelines.htm

Registration form is available on the CIRAS website at:
http://ciras.massey.ac.nz/registration.asp

Accommodation information is available on the website at:
http://ciras.massey.ac.nz/accommodation.asp

Citizens of some countries require Visa to enter New Zealand. Please check with the nearest New Zealand Immigration Office (http://www.immigration.govt.nz/Migrant/Stream/Visit/) whether you need Visa to travel to New Zealand. Please apply early, if you need to.

Please send any enquiries regarding your paper or the conference to S.C.Mukhopadhyay@massey.ac.nz

We look forward to seeing you at the conference and thank you for your contribution.

Kind regards
